

Highlights

WAGER: Within-cell Antisymmetric Gain Evaluation of Resolution

- Exact finite-sample identity splits a model-pair score gain into prior and alignment
- Extends to the full Bregman-score family with large-sample and sensitivity theory
- Leave-one-out transport removes an exact $(n_c - 1)/n_c$ plug-in attenuation bias
- A published debiasing method’s mean-recall gain is overwhelmingly prior-driven
- Cross-domain validation spans vision and text with one unmodified estimator
